Experiment 2

Average Price of Products Sold Using NumPy

Aim

To calculate the average price of products sold during the past month using NumPy arrays and mathematical operations.

Procedure

1. Import the NumPy library.
2. Create a 3×3 NumPy array named sales_data, where each row represents the sales data of a different product.
3. Store the product price values in the array.
4. Use np.mean(sales_data) to calculate the average of all the array elements.
5. Store the calculated value in a variable named avg_price.
6. Display the average price using the print() statement.

Code

```
import numpy as np

sales_data = np.array([

   [100, 150, 200],

   [120, 180, 240],

   [90, 160, 210]

])

avg_price = np.mean(sales_data)

print("Average price:", avg_price)
```

Result

Thus, the average price of the products sold during the past month was calculated successfully using NumPy arrays.

Output

```
== RESTART: D:/fundamentals of data science/experiment 2/experiment 2 code.py =
Average price: 161.11111111111111
```
