Experiment 7

Customer Order Analysis Using Pandas

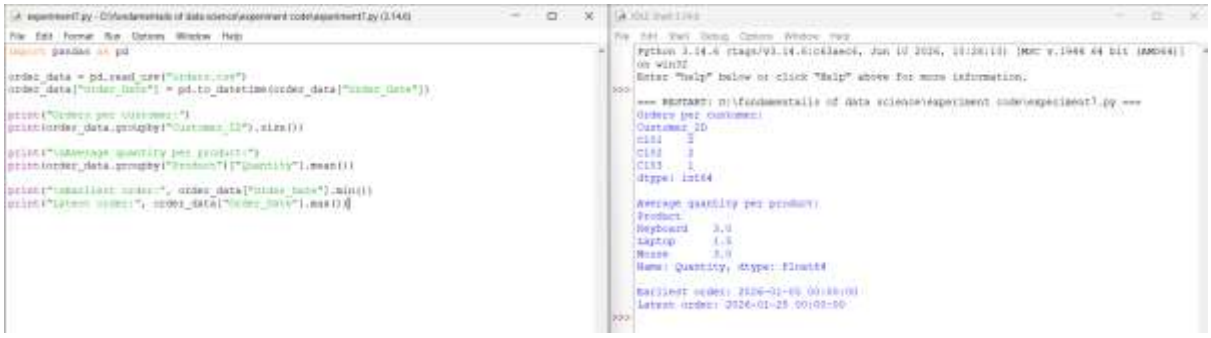

Aim:

To write a Python program using Pandas DataFrame operations to calculate the number of orders made by each customer, the average order quantity for each product, and the earliest and latest order dates.

Procedure:

1. Import the Pandas library.
2. Create a DataFrame containing customer IDs, order dates, product names, and quantities.
3. Convert the order date column into datetime format using pd.to_datetime().
4. Use groupby() and size() to count the orders made by each customer.
5. Use groupby() and mean() to calculate the average quantity for each product.
6. Use min() and max() to find the earliest and latest order dates.
7. Display the results.

Output:

Result:

The customer order dataset was successfully analyzed using Pandas. The number of orders per customer, average product quantities, and earliest and latest order dates were obtained.
