Experiment 9

Property Data Analysis Using Pandas

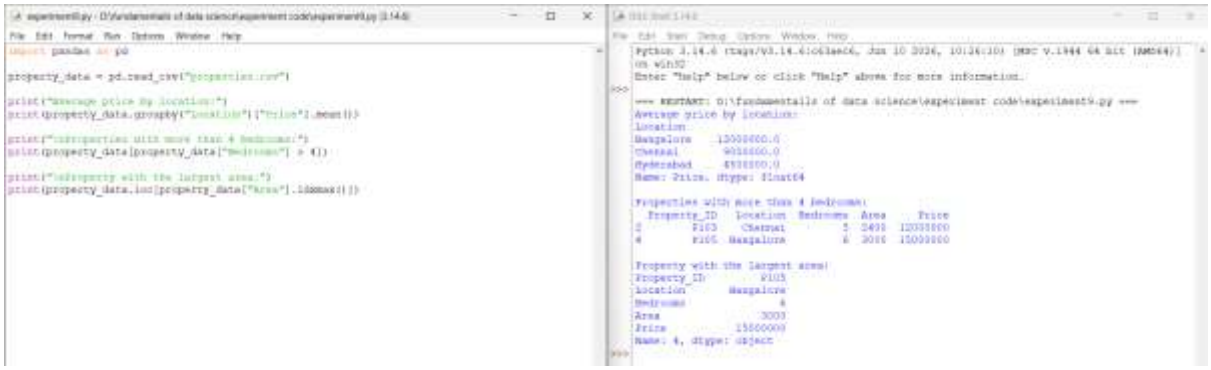

Aim:

To write a Python program using Pandas DataFrame operations to calculate the average listing price of properties in each location, count properties with more than four bedrooms, and identify the property with the largest area.

Procedure:

1. Import the Pandas library.
2. Create a DataFrame containing property ID, location, bedrooms, area, and listing price.
3. Use groupby() and mean() to calculate the average listing price for each location.
4. Apply a filtering condition to select properties with more than four bedrooms.
5. Use idxmax() on the area column to find the index of the property with the largest area.
6. Retrieve and display the details of that property.
7. Display all the results.

Output:

Result:

The property dataset was successfully analyzed using Pandas. The average listing price for each location was calculated, properties with more than four bedrooms were identified, and the property with the largest area was found.
